

**DISK DRIVE PULSE WIDTH MODULATING A VOICE COIL MOTOR  
USING MODEL REFERENCE CURRENT FEEDBACK**

**CROSS REFERENCE TO RELATED APPLICATIONS AND PATENTS**

This application is related to U.S. Patent No. 5,898,283 entitled "VOLTAGE FEEDFORWARD CONTROL SYSTEM FOR A SPINDLE MOTOR OF A DISK DRIVE".

This application is also related to co-pending U.S. Patent Application Ser. No. 10/376,819 entitled "DISK DRIVE COMPRISING CURRENT SENSE CIRCUITRY FOR A VOICE COIL MOTOR" filed on 2/28/2003, co-pending U.S. Patent Application Ser. No. 10/609,240 entitled "DISK DRIVE CONTROLLING RIPPLE CURRENT OF A VOICE COIL MOTOR WHEN DRIVEN BY A PWM DRIVER" filed on 6/27/2003, and co-pending U.S. Patent Application Ser. No. 09/704,195 entitled "DISK DRIVE EMPLOYING SEEK TIME VCM IR VOLTAGE CALIBRATION FOR VELOCITY CONTROL OF AN ACTUATOR ARM" filed on 10/31/00.

The disclosures of the above identified U.S. patent and patent applications are incorporated herein by reference.

**BACKGROUND OF THE INVENTION**

**Field of the Invention**

The present invention relates to disk drives for computer systems. More particularly, the present invention relates to a disk drive pulse width modulating a voice coil motor using model reference current feedback.

**Description of the Prior Art**

A disk drive typically employs a voice coil motor (VCM) comprising a voice coil which interacts with permanent magnets to rotate an actuator arm about a pivot. A head is connected to a distal end of the actuator arm to actuate it radially over the surface of a disk in order to "seek" the head to a target data track. Once the head is positioned over the target data track, the VCM

1 servo system performs a "tracking" operation wherein the head is maintained over a centerline of  
2 the data track while writing data to or reading data from the disk.

3 Conventionally the VCM has been driven using an H-bridge amplifier operating in a linear  
4 mode which leads to inefficient power dissipation since the transistors are driven with constant  
5 current. Driving the H-bridge amplifier in a pulse width modulated (PWM) mode increases the  
6 efficiency by driving the transistors in a switching mode (on-off) so that power dissipation occurs  
7 only when the transistors are switched on. FIG. 1 shows a prior art transconductance amplifier  
8 configuration for driving the VCM in a PWM mode using current feedback. The VCM comprises  
9 a voice coil 2 which has an intrinsic inductance (L) and resistance (R). The voice coil 2 is driven  
10 by an H-bridge amplifier comprising driver switches 4A-4D. A sense resistor R1 is connected in  
11 series with the voice coil 2, and an amplifier 6 amplifies the voltage across the sense resistor R1 to  
12 generate a voltage 8 representing the amplitude of current flowing through the voice coil 2.

13 The feedback loop established through amplifier 6 turns the voltage driver into a current  
14 driver, accomplishing the change from a voltage amplifier into a transconductance amplifier  
15 (which turns a voltage command into a current output). The voltage 8 representing the actual  
16 voice coil current is subtracted at node 10 from a voltage command  $u(k)$  12 representing a desired  
17 voice coil current. The resulting voltage at node 10 is amplified by a high gain error amplifier 14  
18 that generates a voltage command 16 applied to a first input of comparators 18A and 18B. A  
19 signal generator 20 generates a triangle waveform 22 applied to a second input of the  
20 comparators 18A and 18B. The comparators 18A and 18B generate PWM signals 24A and 24B  
21 having a duty cycle proportional to the current command 16. The PWM signals 24A and 24B are  
22 applied to switch control 26 which controls the driver switches 4A-4D in order to control the  
23 voltage applied to the voice coil 2. Resistor R4 and capacitor C1 in the feedback path between  
24 the current command 16 and the input voltage of error amplifier 14 provide lead compensation to  
25 compensate for the lag caused by the L/R time constant of the voice coil 2.

26 There are several drawbacks associated with driving a VCM in a PWM mode as illustrated  
27 in FIG. 1. For example, the various analog components of the error amplifier 14 increase the

1 complexity and cost of the VCM driver circuitry. In addition, the periodic operation of the PWM  
2 mode introduces additional lag into the transconductance loop which decreases the loop  
3 bandwidth. The lead network provided by resistor R4 and capacitor C1 helps compensate for the  
4 additional lag, but the lead network must be designed conservatively to prevent instability due to  
5 the voice coil resistance drifting as the temperature fluctuates. The PWM lag can also be reduced  
6 by increasing the frequency of the PWM signals 24A and 24B, but this reduces the efficiency  
7 advantage of operating in a PWM mode. Due to these drawbacks, the VCM has been driven in a  
8 PWM mode using the configuration of FIG. 1 only during low bandwidth portions of the seek  
9 waveform. During short seeks and tracking operations, the H-bridge amplifier has been driven in  
10 a conventional linear mode so that the bandwidth can be increased without losing stability.

11 There is, therefore, a need to reduce the cost and increase power efficiency of the VCM  
12 driver circuitry in a disk drive.

### 13 SUMMARY OF THE INVENTION

14 The present invention may be regarded as a disk drive comprising a disk, a head, and a  
15 voice coil motor (VCM) for actuating the head radially over the disk, the VCM comprising a  
16 voice coil. A plurality of driver switches control a voltage applied to the voice coil, and a pulse  
17 width modulated (PWM) signal generator generates PWM control signals applied to the driver  
18 switches. A control law block generates an acceleration command in response to a commanded  
19 current and at least one estimated state of the VCM, and a command to timing block generates a  
20 plurality of PWM timing signals in response to the acceleration command. A PWM controller  
21 generates the PWM control signals applied to the driver switches in response to the PWM timing  
22 signals, wherein the command to timing block, PWM controller, driver switches, and voice coil  
23 comprise a plant transfer function. A current detector detects a current flowing through the voice  
24 coil, and a plant model comprising a model transfer function generates the estimated state of the  
25 VCM in response to the detected current flowing through the voice coil. A correction block,  
26 responsive to the detected current, adjusts the PWM timing signals so that the plant transfer  
27 function substantially matches the model transfer function.

1 In one embodiment, the at least one estimated state of the VCM comprises at least one of  
2 a position, velocity, and acceleration of the VCM.

3 In another embodiment, the PWM timing signals comprise a PWM cycle time, a Tforward  
4 time interval of the PWM cycle time wherein a positive control voltage is applied to the voice  
5 coil, a Treverse time interval of the PWM cycle time wherein a negative control voltage is applied  
6 to the voice coil, and a Tdead time interval of the PWM cycle time wherein a substantially zero  
7 control voltage is applied to the voice coil. The correction block adjusts the Tdead time interval  
8 to control a magnitude of a ripple current flowing through the voice coil. In one embodiment, the  
9 correction block adjusts the Tdead time interval to maintain a substantially constant L/R ratio  
10 where L is an effective inductance of the voice coil and R is a resistance of the voice coil.  
11 Adjusting the Tdead time interval adjusts the effective inductance L of the voice coil 34 since the  
12 effective inductance L is a function of the actual ripple current flowing through the voice coil 34.

13 In yet another embodiment, the driver switches connect a supply voltage to the voice coil,  
14 and the correction block adjusts the PWM timing signals in response to the supply voltage. In  
15 one embodiment, the correction block adjusts the Tforward and Treverse time intervals in  
16 response to the supply voltage.

17 In another embodiment, the resistance R of the voice coil changes with temperature drift,  
18 and the correction block adjusts the Tforward and Treverse time intervals in response to a  
19 magnitude of the resistance R. In one embodiment, the correction block adjusts a saturation limit  
20 of the Tforward and Treverse time intervals in response to a magnitude of the resistance R. In  
21 still another embodiment, the correction block adjusts a saturation limit of the Tforward and  
22 Treverse time intervals in response to a magnitude of the resistance R and to a magnitude of a  
23 torque constant Kt of the VCM.

24 The present invention may also be regarded as a method of operating a disk drive, the disk  
25 drive comprising a disk, a head, a voice coil motor (VCM) for actuating the head radially over the  
26 disk, the VCM comprising a voice coil, and a plurality of driver switches for controlling a voltage  
27 applied to the voice coil. An acceleration command is generated in response to a commanded

1 current and at least one estimated state of the VCM, and a plurality of PWM timing signals are  
2 generated in response to the acceleration command. PWM control signals are applied to the  
3 driver switches in response to the PWM timing signals. A current flowing through the voice coil  
4 is detected, and the estimated state of the VCM is generated in response to the detected current  
5 flowing through the voice coil. The PWM timing signals are adjusted in response to the detected  
6 current so that a plant transfer function of the VCM and driver switches substantially matches a  
7 model transfer function

## 8 **BRIEF DESCRIPTION OF THE DRAWINGS**

9 FIG. 1 shows a prior art disk drive employing a transconductance amplifier configuration  
10 for driving the VCM in a PWM mode using current feedback.

11 FIG. 2 shows a disk drive according to an embodiment of the present invention employing  
12 PWM signal generator comprising a PWM controller for generating PWM control signals in  
13 response to PWM timing signals, and a correction block for adjusting the PWM timing signals to  
14 adjust a transfer function of the VCM plant to match a model transfer function.

15 FIG. 3 shows an embodiment of the present invention wherein the correction block adjusts  
16 the PWM timing signals to control a ripple current flowing through the voice coil of the VCM.

17 FIG. 4 shows details of a command to timing block according to an embodiment of the  
18 present invention wherein an acceleration command is scaled and limited relative to a resistance  $R$   
19 of the voice coil.

20 FIG. 5 shows details of a command to timing block according to an embodiment of the  
21 present invention wherein the acceleration command is further scaled and limited relative to a  
22 torque constant  $K_t$  of the VCM.

## 23 **DESCRIPTION OF THE PREFERRED EMBODIMENTS**

24 FIG. 2 shows a disk drive according to an embodiment of the present invention  
25 comprising a disk 28, a head 30, and a voice coil motor (VCM) 32 for actuating the head 30  
26 radially over the disk 28, the VCM 32 comprising a voice coil 34. A plurality of driver switches  
27 36A-36D control a voltage 37 applied to the voice coil 34, and a pulse width modulated (PWM)

1 signal generator 38 generates PWM control signals 40 applied to the driver switches 36A-36D. A  
2 control law block 42 generates an acceleration command 44 in response to a commanded current  
3 46 and at least one estimated state 48 of the VCM 32. A command to timing block 50 generates  
4 a plurality of PWM timing signals 52 in response to the acceleration command 44. A PWM  
5 controller 54 generates the PWM control signals 40 applied to the driver switches 36A-36D in  
6 response to the PWM timing signals 52. The command to timing block 50, PWM controller 54,  
7 driver switches 36A-36D, and voice coil 34 comprise a plant transfer function. A current detector  
8 56 detects a current 58 flowing through the voice coil 34, and a plant model 60 comprising a  
9 model transfer function generates the estimated state 48 of the VCM 32 in response to the  
10 detected current 58 flowing through the voice coil 34. A correction block 62, responsive to the  
11 detected current 58, adjusts the PWM timing signals 52 so that the plant transfer function  
12 substantially matches the model transfer function.

13 The control law 42 of FIG. 2 implements any suitable compensation algorithm for  
14 generating the acceleration command 44 relative to the estimated state or states 48. In one  
15 embodiment, the estimated state 48 includes at least one of a position, velocity, and acceleration  
16 of the VCM 32. The plant model 60 estimates the VCM 32 response or motion when a current is  
17 applied to the voice coil 34 (as detected by the current detector 56). The estimated state 48 is a  
18 filtered representation of the actual, noisy state of the VCM 32. In state space control theory, the  
19 plant model 60 is adjusted to match the behavior of the controlled plant so as to minimize the  
20 error in the estimated state 48. However in the embodiment of FIG. 2, the plant behavior is  
21 adjusted to match the model instead. Since the plant behavior is made more constant and stable  
22 through this adjustment, fixed compensation techniques become much more effective at  
23 improving the plant behavior. The control law 42 can now also use simpler, conventional  
24 compensation techniques to compensate for the lag inherent with driving the VCM 32 in a PWM  
25 mode without having to account for variations in the plant transfer function, such as the resistance  
26 R of the voice coil 34 fluctuating with temperature. Also, the resulting performance will be more  
27 predictable compared to a conventional PWM and VCM combination.

FIG. 3 shows an embodiment of the present invention wherein the current detector 56 generates an average current  $I_{avg}$  68 and a ripple current  $I_{ripple}$  70 flowing through the voice coil 34 over a PWM cycle time. The correction block 62 processes the average current  $I_{avg}$  68 and the ripple current  $I_{ripple}$  70 in order to adjust the PWM timing signals 52 to maintain a substantially constant  $L/R$  ratio, wherein  $L$  is the inductance and  $R$  is the resistance of the voice coil 34. Maintaining a substantially constant  $L/R$  ratio allows the control law 42 to compensate for the associated lag using any suitable compensation algorithm. A suitable method for generating the average current  $I_{avg}$  68 over a PWM cycle time is disclosed in the above-identified co-pending patent application entitled "DISK DRIVE COMPRISING CURRENT SENSE CIRCUITRY FOR A VOICE COIL MOTOR". A suitable method for generating the ripple current  $I_{ripple}$  70 over a PWM cycle time and for adjusting the PWM timing signals 52 to maintain a substantially constant  $L/R$  ratio is disclosed in the above-identified co-pending patent application entitled "DISK DRIVE CONTROLLING RIPPLE CURRENT OF A VOICE COIL MOTOR WHEN DRIVEN BY A PWM DRIVER".

In the aforementioned patent application, the PWM timing signals 52 comprise a PWM cycle time, a  $T_{forward}$  time interval of the PWM cycle time wherein a positive control voltage is applied to the voice coil 34, a  $T_{reverse}$  time interval of the PWM cycle time wherein a negative control voltage is applied to the voice coil 34, and a  $T_{dead}$  time interval of the PWM cycle time wherein a substantially zero control voltage is applied to the voice coil 34. The correction block 62 adjusts the  $T_{dead}$  time interval to control the magnitude of the ripple current  $I_{ripple}$  70 flowing through the voice coil 34. In one embodiment, the correction block 62 adjusts the  $T_{dead}$  time interval to maintain a substantially constant  $L/R$  ratio where  $L$  is an effective inductance of the voice coil 34 and  $R$  is a resistance of the voice coil 34. Adjusting the  $T_{dead}$  time interval adjusts the effective inductance  $L$  of the voice coil 34 since the effective inductance  $L$  is a function of the actual ripple current flowing through the voice coil 34.

Also in the embodiment of FIG. 3, the command to timing block 50 adjusts the PWM timing signals 52 in response to a magnitude of the supply voltage 37 driving the voice coil 34 in

1 order to maintain a substantially constant voltage gain for the PWM controller 54. In one  
2 embodiment, the Tforward and Treverse time intervals are adjusted inversely proportional to a  
3 magnitude of the supply voltage 37. For example, the Tforward and Treverse time intervals can  
4 be adjusted directly, or the frequency for generating the intervals can be adjusted proportional to  
5 the magnitude of the supply voltage 37 while holding the PWM cycle time constant. Further  
6 details of this embodiment are disclosed in the above-identified U.S. Patent entitled "VOLTAGE  
7 FEEDFORWARD CONTROL SYSTEM FOR A SPINDLE MOTOR OF A DISK DRIVE".

8 FIG. 4 shows an embodiment of the command to timing block 50 according to an  
9 embodiment of the present invention wherein the voltage saturation characteristics of the plant  
10 transfer function are held constant by scaling 72 and limiting 74 the acceleration command 44  
11 relative to the resistance R 76 of the voice coil 34. In conventional VCM control systems the  
12 supply voltage is typically allowed to limit the response. However, since the supply voltage varies  
13 substantially and rapidly, the supply voltage becomes a source of variation in performance,  
14 therefore the typical control system is designed with extra margin to avoid supply voltage limits.  
15 By implementing a limit that is held constant, the control system can use the entire range of  
16 actuation, including saturation, with predictable and repeatable characteristics, thereby allowing  
17 precompensation to be adjusted without regard to supply voltage amplitude. In one embodiment,  
18 the VCM coil 34 can be adjusted to compensate for the lower saturation voltage by rewinding the  
19 voice coil 34 with fewer turns, ensuring that plant maximum performance can still be achieved  
20 (and may actually increase plant performance). The resistance R 76 of the voice coil 34 may be  
21 estimated using any suitable technique, such as the technique disclosed in the above-identified co-  
22 pending patent application entitled "DISK DRIVE EMPLOYING SEEK TIME VCM IR  
23 VOLTAGE CALIBRATION FOR VELOCITY CONTROL OF AN ACTUATOR ARM".

24 In the embodiment of FIG. 4, the thresholds of limit 74 are computed as  $\pm(I_{\max} \cdot R)$ ,  
25 where  $I_{\max}$  is a predetermined maximum current flowing through the voice coil 34. Also in the  
26 embodiment of FIG. 4, the output of the limit 74 can be adjusted (via adder 78) relative to a back  
27 EMF voltage 80 across the voice coil 34. The output of adder 78 is then used to compute 82 the

1 Tforward and Treverse time intervals applied to a PWM generators timers block 84. The PWM  
2 generators timers block 84 is responsive to a T\_CYCLE counter 86 which generates the PWM  
3 cycle time, a FREQ counter 85 adjusted in response to a magnitude of the supply voltage 37, and  
4 a ripple control block 88 for adjusting the Tdead time interval (see the above-identified co-  
5 pending patent application entitled "DISK DRIVE CONTROLLING RIPPLE CURRENT OF A  
6 VOICE COIL MOTOR WHEN DRIVEN BY A PWM DRIVER").

7 Another significant source of variation is the torque constant Kt of the VCM 32 which can  
8 vary by several percent over the travel range of the head 30. FIG. 5 shows an embodiment of the  
9 command to timing block 50 according to an embodiment of the present invention wherein the  
10 acceleration command 44 is further scaled 72 relative to a torque constant Kt 90 of the VCM 32,  
11 and the thresholds of limit 74 are computed as  $\pm(I_{max} \cdot R/Kt)$ . This accounts for changes in the  
12 torque constant Kt 90 due to voice coil magnetic structure position dependencies and temperature  
13 drift, thereby allowing the control system to be designed with the assumption that the acceleration  
14 command 44 will produce proportional motion acceleration. In one embodiment, the voice coil  
15 34 is rewound to nominally 30% lower voltage so that the same force is generated at less than full  
16 duty cycle (70%), leaving adequate voltage headroom for thermal resistance measurements, back  
17 EMF voltages, etc.
